GUIDE

Will a wheelchair fit in my car trunk?

Trunk liters do not answer this: measure the opening, the narrowest point and the loading lip, then check someone can actually lift it in.

July 28, 2026 · 5 minute read

The short answer

Usually yes, but "a wheelchair" covers a very wide range of objects and "a trunk" covers an even wider one. The useful question is not whether a wheelchair fits in a trunk in principle. It is whether **this** chair fits **this** car, loaded by **the person who will actually be doing the loading**, repeatedly, in a car park, in the rain, while someone waits.

That reframing matters because it changes what you are shopping for. Most disappointment here comes from measuring the wrong thing once, rather than from buying the wrong chair.

Three things decide it, not one

- **The folded shape of the chair**, not its folded volume. A chair that folds narrow but stays long behaves completely differently from one that folds short and stays tall.
- **The trunk opening**, not the trunk space. Many cars have generous space behind a small, high, awkwardly shaped aperture. The lip height, the angle of the tailgate and anything fixed inside, a cargo shelf, a rigid trunk floor, a load cover, a spare wheel housing, all reduce what you can actually post through.
- **Who lifts it.** This is the factor most often left out of the decision, and it is the one that decides whether the arrangement survives past the first two weeks.

Different chairs behave very differently

- **Attendant propelled transit chairs** have small rear wheels and are generally the lightest and the most compact when folded. They are the easiest to put in a trunk and the least independent for the person sitting in them, because they cannot be self propelled.
- **Self propelled chairs** have large rear wheels, which add width and bulk. Many have quick release axles, so the wheels come off in seconds and the frame goes in separately. If you are comparing chairs, ask about this specifically: it often matters more than the folded dimensions on the page.
- **Rigid lightweight chairs** do not cross fold. The backrest drops and the wheels come off, and the result is frequently a smaller and lighter load than a folding chair, in two or three pieces rather than one.
- **Powerchairs and mobility scooters** are a different category. Batteries, motors and frames mean most will not go into a car trunk unless the product is designed to separate into parts, and some cannot reasonably be lifted by one person at all. Here the honest route is usually a hoist, a ramp, or a vehicle chosen around the chair.

Weight decides more than dimensions

A chair is almost never lifted in the position a spec sheet implies. It is lifted at arm's length, over a lip, with a twist, by someone who is also holding a door open. The load you feel is greater than the number written down, and it is felt again on the way out.

So test the lift, not the figure. Lift it from the ground to trunk height, put it in, take it out, and then do that a second and third time. A lift that is merely possible once is not a lift that works on a Tuesday in February.

When buying something will not solve this

Sometimes the problem is not the chair, and buying a lighter one is an expensive way to learn that.

If the person doing the loading has a shoulder, back or grip problem, there is no chair light enough to fix it. The load may come down, but the movement that causes the pain does not change. What helps is a trunk hoist, a different vehicle with a lower load height, a folding ramp, help at the other end of the journey, or simply agreeing that two people do the car. Those are the real options, and none of them is a lighter wheelchair.

The other version of this: if the chair genuinely fits the person, and the car is the constraint, changing the chair is the wrong end to change. A chair that is lighter but less supportive trades the user's whole day for ninety seconds at the curb. That is a poor trade and it tends to be made by whoever is not sitting in the chair.

Why this is an adaptation rather than a purchase

Trunk loading is rarely a settled question. Strength changes, cars change, the amount of walking someone does at the far end changes, and a setup that worked last winter can stop working without anyone deciding it should. That is the whole point of Mobility Adaptation: you are not buying the answer once, you are keeping the way someone moves matched to how things actually are. Expect to revisit this, and treat revisiting it as normal rather than as a setback.

What to measure and what to ask

Take five minutes with a tape measure before you compare any products.

- The **height from the ground to the trunk lip**, and the height of the lip itself.
- The **narrowest point of the opening**, measured at the actual aperture, not across the trunk floor.
- The **usable depth and height inside** with the cargo shelf or load cover in place, and again with it removed.
- What is **permanently in there**: a raised floor, a subwoofer, a spare wheel, a stroller you cannot leave behind.

- Whether the **tailgate clears** the person loading, and how much room the car needs behind it to open at all. A trunk that works in your driveway may be unusable in a tight parking space.

Then ask, of any chair you are considering: what does it weigh as you would lift it, with the cushion and any accessories on; do the wheels come off without tools; how many pieces does it become; what are its folded dimensions in all three directions; and can you try the lift, with that chair, before committing to it.

If the answer to the last one is no, that is worth knowing too.

General information, not medical advice. If fit, posture, pressure relief or fall risk is part of your decision, speak to an occupational therapist.

SILVERA MOBILITY
